Rates of common mental health disorders (CMDs) in Northern Ireland, England, Scotland and Wales (1991-2022): evidence from BHPS/UKHLS Understanding Society Survey

Suzanne Barrett BSc PhD PGCHET CPsychol

Research Psychologist

NICRN Mental Health, Impact Research Centre, Northern HSC Trust

Background

- Widely reported that the Northern Ireland [NI] population, either directly or indirectly, accounts for higher rates of common mental disorders (CMDs) compared to other UK nations (Betts and Johnston, 2017);
- Citizens with SMIs have reduced life expectancy of 15-20 years due to poor physical health compared to GP (DOHNI, 2001: p.61).
- NISHS - highest prevalence of mental illness in the UK post-World Economic Crisis (Bunting et al., 2012, 2013);
- Morbidity 25% higher than rest of the UK (O'Neill & Rooney, 2018);
- Mortality: Samaritans commissioned report (Bambra et al., 2017) found prior to 2017; incidence of around 16 deaths per 100 000 individuals per year related to mental illness in NI.
- Northern Ireland has been exposed to a long period of civil conflict and has higher 12-month and life-time prevalence rates of PTSD compared to other countries affected by conflict, including South Africa, Israel / Lebanon (Bunting et al., 2012, 2013).

Background

- Publication of a new Mental Health Strategy (2021-2031) by DOHNI.
- Measurable outcomes “Better mental health among the wider population, evidenced by a reduction of % of population with GHQ-12 scores ≥ 4 (signifying possible mental health problem).”
- **Aim:** to explore the available GHQ-12 population data from National Surveys conducted in the UK to determine if evidence supports assertion that NI has higher rates of mental illness compared to rest UK.
- **Hypothesis:** NI would demonstrate comparatively poorer mental health compared to other UK nations over the time period 1991 to 2021, as measured by the GHQ-12.

Method

- In Dec 2022/Jan 2023 identified surveys containing GHQ-12 through searches of the UK Data Service, Government (and Government agency) websites and UK's Catalogue of Mental Health Measures.
- Sourced available microdata from UK Data Service.
- Sourced aggregate data from Government websites where no microdata available (affecting NI only).
- **Analysis:** GHQ-12 "Caseness" data were explored:
 - cross-sectionally by UK nation and year of data collection
 - longitudinally (within-country) using comparative inferential tests of significance (Kruskal-Wallis and χ^2 tests, with multiple comparisons to detail national in-year differences)
 - effect sizes (to control for sample size variation and improve interpretability of findings).
 - Characterisation of samples X GHQ-12 "Missingness" against census
 - Examination of sample depletion/renewal over time

Method

Table 2: GHQ-12 data in UK Longitudinal Studies Surveys

1 Surveys of Psychiatric Morbidity - marginalised populations	2 1970 British Cohort Study (BCS70)
3 Born in Bradford (BiB)	4 The Cambridge Study in Delinquent Development

Results

GHQ-12		Average Total Available Yrs	S.D.	Average 2001+	S.D.
0	NI*	57.41%	3.86%	57.41%	3.86%
1 to 3		24.35%	3.11%	24.35%	3.11%
4+		18.23%	1.78%	18.23%	1.78%
		=15722 (mean =749)	372	n=15722 (mean =749)	372
0	England	53.57%	2.47%	54.66%	2.05%
1 to 3		26.69%	2.14%	25.61%	1.49%
4+		19.75%	1.27%	19.73%	1.47%
		n=560525 (mean =18081)	10478	477508 (mean =22738)	9591
0	Scotland	56.61%	2.64%	57.90%	1.86%
1 to 3		25.06%	2.38%	23.70%	1.24%
4+		18.33%	1.45%	18.40%	1.64%
		n=55847 (mean =1802)	1077	48278 (mean =2299)	948
0	Wales	51.38%	4.65%	53.82%	3.02%
1 to 3		26.42%	2.71%	25.32%	1.78%
4+		22.17%	2.89%	20.83%	2.19%
		n=32748 (mean =1056)	618	27979 (mean =1332)	564
	n	664880		569489	
	χ^2 (df)	412.31 (6)		253.17 (6)	
	p	0.00		0.00	
	V min	0.01 2		0.01 2	

Hypothesis not fully supported: estimates indicate that **participants from NI had better mental health** overall compared to neighbouring UK countries England ($V=0.01$) and Wales ($V=0.06-0.07$), and showed no significant difference from Scotland ($p>0.05$).

Discussion

- **Body of evidence:** predominantly uses clinical assessment tools and robust diagnostic procedures to estimate rates of mental ill health *and related variables* in UK populations to support a narrative of greater Mental Ill health in NI, rather than the self-report short-form assessment of Mental Health [GHQ-12] used in the BHPS/UKHLS to measure mental health in individuals from selected UK households.
- **Internal review of GHQ-12 data from UK** found lower rates of “Persons with no symptoms” (GHQ-12 = 0; Average = 52%) and higher rates of “Persons at Risk” (GHQ-12 = 1-3; Average = 29%) and “Probable Cases” (GHQ-12 = 4+; Average = 19% i.e. a fifth) in NI i.e. a less favourable profile compared to:
 - (i) findings for NI from BHPS/UKHLS *Understanding Society* and
 - (ii) Health Survey data from elsewhere in the UK (England Average Estimates = 60-61%, 24-25%, 14-15%; Scotland Average Estimates = 58-61%, 24-25%, 15-17% respectively) .

- **Study Design Effects** may impact results and/or confound conclusions drawn from Mental Health data.
 - E.g. BHPS/UKHLS Survey initiation and/or sample replenishment coincided with positive improvements in participants' mental health measures.
- **Renewed household recruitment** potential to create errors of conflation in “cross-sectional” data, masking mental health issues in the population previously assessed. Query quantification fallacies relating to survey stability and participant/household retention?
- Data from UK Health Surveys truly “cross-sectional”. **Repeat assessment** and the **interval to retest** may affect GHQ-12 responses cumulatively, through “social desirability” responding, [in]sensitivity to questions and/or through sample aging effects that may not be obvious in short to mid-term.
- Panel/Household surveys can show an **age selection bias** of sorts (underrepresentation of 16-24 year olds and an over representation of 26-45 year olds i.e. “household reference persons”) due to life course trends affecting stable household establishment.

Discussion

- **How comparable are the BHPS/UKHLS cross-sectional weighted samples of UK nations? How representative are the cross-sectional weighted samples of the underlying populations?**
- For GHQ-12 Completers, UK nations similar across Waves prior to NI joining (1991-2000) with regard to age & sex distributions of the adults 16+, as well as average household size. Marital status profiles to a lesser extent. Age and sex distribution data consistent with data from underlying 1991 and 2001 Censuses.
 - Underlying Census data - had adults 16+ in NI been included in all early Waves of BHPS (Waves 1-10), they would have been younger on average (by up to 2-3 years) more likely to be single (up to 5-7%), less likely to be separated, divorced and/or widowed (by up to 4-6%) during this period.
- After NI joined the survey (2001/2), differences in sociodemographic variables between UK nations increased among GHQ-12 Completers, becoming more noticeable in Wave 9 and Wave 11 BHPS and Wave 1 of UKHLS. E.g. NI highest proportion of single persons; lowest % BAME community.
- NI diverged from patterns elsewhere in UK in Census 2021/22 i.e. nation with largest proportion (28+%) of persons 16+ with a LLTI reported to date. In contrast, fewer GHQ-12 Completers from NI have LLTI compared to other UK nations.
